

# Gleichenia inclusisora

## COMMON NAME

tangle fern

## SYNONYMS

None (first described in 2012)

## FAMILY

Gleicheniaceae

## AUTHORITY

*Gleichenia inclusisora* Perrie, L.D.Sheph., et Brownsey

## FLORA CATEGORY

Vascular – Native

## ENDEMIC TAXON

Yes

## ENDEMIC GENUS

No

## ENDEMIC FAMILY

No

## STRUCTURAL CLASS

Ferns

## CURRENT CONSERVATION STATUS

2017 | At Risk – Naturally Uncommon | Qualifiers: DP, RR

## PREVIOUS CONSERVATION STATUS

2012 | At Risk – Naturally Uncommon | Qualifiers: DP, RR

## BRIEF DESCRIPTION

Tangle fern. Rhizomatous. Fronds umbrella-like, upper surface green, glossy, undersides white (or blue-green). Sori in clusters of three or four, these embedded up to  $\frac{3}{4}$  of their depth in a small pit in the lower frond surface.

## DISTRIBUTION

Endemic. New Zealand: North and South Islands from Te Moehau to Westland but often absent from large parts of this range.

## HABITAT

Lowland to montane (850 m on Te Moehau). Inhabiting pakihi (wet, infertile heaths) and open shrubland/treeland. *Gleichenia inclusisora* has been recorded growing with *G. alpina* and *G. microphylla*, but it is most commonly associated with *G. dicarpa*.

## DETAILED DESCRIPTION

Terrestrial fern. **Rhizomes** long-creeping, 1–3mm diameter, brown, with stipes arising at intervals of 5–90mm (or more), scaly. **Rhizome scales** sparse to numerous, 0.5–1.2 × 0.5–0.8mm, ovate to orbicular, dark brown to nearly black, margins entire or nearly so, peltate, bullate. **Stipes** 40–1100 mm long, 1.0–2.5mm diameter, widest distally, proximally dark brown, distally straw-green when young or brown when old, glabrous except for occasional, proximal scales that are like those of the rhizome. **Rachis buds** 2.0–3.1 × 1.2–2.1 mm, often not producing a rachis so that fronds form a single tier of pinnae, but sometimes 2–4 tiers, with rachis inter-tier lengths of 15–280 mm. **Rachis bud scales** 1.5–2.5 × 1.0–1.5 mm, ovate, marginate, dark brown with a pale brown or clear margin, ciliate to erose, peltate. **Pinnae** 50–950+ × 50–300 mm, with 0–6 pseudodichotomous branchings. **Pinna buds** similar to rachis buds but generally smaller. **Distal costae (nerves)** appearing tetragonal or nearly so on the adaxial surface, with lateral ridges. **Proximal costae** glabrescent, straw-green when young, brown when old. **Gamma costae** 10–40mm long, with 0–4 pairs of ultimate leaflets; indument similar to beta costae but sparser. **Beta costae** 25–135mm long, with 5–26 pairs of ultimate leaflets and a terminal ultimate leaflet 10–44 mm long; adaxially with long-ciliate, reduced scales that are abundant and orange-brown when young or sparse and white when old; abaxially with a mixture of scales like those on the pinna buds and ultimate segments, glabrescent. **Longest ultimate leaflets** 18–59mm long, with 15–47 pairs of ultimate segments. **Alpha costae** adaxially glabrous (or with occasional reduced scales like those of the beta costae when young), abaxially with scales like those of the ultimate segments. **Ultimate segments** 0.7–1.4 × 0.9–1.4 mm, adaxially green and glabrous, abaxially white (sometimes glaucous) and abundantly (when young) to sparsely scaly, abaxial surface flat to recurved 90° but lateral margins at most only slightly raised (not pouched), apices rounded and revolute. **Scales on abaxial surface of ultimate segments** 0.3–0.8 × 0.3–0.6 mm, orbicular to ovate, with dark brown centre and pale brown margins, long-ciliate, peltate, bullate; similar but larger (to 1.0 mm long), ovate scales covering young ultimate leaflets. **Sori** 0.4–0.5 mm diameter, each comprising three pale yellow sporangia embedded to c. ¾ of their depth in a pit within the abaxial surface of the lamina; one sorus per ultimate segment, in the proximal acroscopic corner. **Spores** trilete, yellow.

## SIMILAR TAXA

*Gleichenia inclusisora* is distinguished from the other three New Zealand species of *Gleichenia* (*G. alpina*, *G. dicarpa* and *G. microphylla*) by the sori which are embedded rather than flush or proud from the lamina; by the bicolorous, orbicular to ovate, peltate scales on the abaxial surfaces of the ultimate segments; by the glabrous stipes; glabrous proximal costae (nerves); by the ultimate segments which are unpouched and abaxially white; and by pinnae that divide pseudodichotomously several times. Of the other three New Zealand species it most often grows with *G. dicarpa* from which *G. inclusisora* can be visually recognised in the field by the shinier upper frond surface, which contrasts strongly with the usually duller *G. dicarpa* upper frond surface.

## PROPAGATION TECHNIQUE

Unknown. Probably best left alone.

## THREATS

*Gleichenia inclusisora* is known from at least 17 sites collectively occupying an area of >300 square kilometres. As *Gleichenia inclusisora* was a chance discovery (Perrie *et al.* 2012), the naming authors note that it is likely to be found elsewhere in New Zealand (especially now that it has been formally described). Perrie *et al.* (2012) using the New Zealand Threat Classification System (Townsend *et al.* 2007) recommended a conservation status of “At Risk – Naturally Uncommon” with a qualifier of “RR” [Range Restricted]. This assessment was accepted by the New Zealand Indigenous Vascular Plant Threat Listing Panel (de Lange *et al.* 2013).

## ETYMOLOGY

**gleichenia**: After the German naturalist and plant physiologist Wilhelm Friedrich (Baron) von Gleichen (1717–1783)  
**inclusisora**: Inklus - Latin, meaning enclosed, and here referring to the sori of *G. inclusisora* being embedded within the lamina
